Historical fire response Interval estimates

PYROSENSE | Urbiztondo, Pangasinan | 12 historical records

Prepared 21 October 2026 | Documentation scenario

ESTIMATED AND SYNTHETIC DATA - These values are not measured historical response performance. Travel estimates use barangay hall proxies; arrival-to-fire-out intervals are generated scenario values.

Average dispatch to incident-location arrival

5.72 min

5 min 43 sec

Average incident arrival to fire out

22.92 min

22 min 55 sec

Matched incident estimates

Record	Stored date	Barangay	Dispatch to arrival (min)	Arrival to fire out (min)
H1	2023-01-01	Poblacion	0.60	27
H2	2023-03-01	Bayaoas	4.69	22
H3	2023-07-01	Pasibi East	12.15	28
H4	2023-08-01	Dalanguiring	5.06	10
H5	2024-01-01	Gueteb	10.25	22
H6	2025-01-01	Poblacion	0.60	22
H7	2025-02-01	Poblacion	0.60	20
H8	2025-05-03	Pasibi West	14.52	30
H9	2025-12-01	Real	7.14	30
H10	2026-01-01	Bayaoas	4.69	17
H11	2026-02-26	Dalanguiring	5.06	25
H12	2026-03-25	Angatel	3.29	22

Averages weight each of the 12 records equally and use the underlying travel values before display rounding. The assumed 2-minute report-to-dispatch delay is excluded from both averages.

Method and location alignment

The estimates preserve the historical record IDs and barangay assignments. No database values, application code, or schema were changed for this PDF.

Travel estimates

Geoapify driving estimates are used for Poblacion, Bayaoas, Pasibi East and Angatel. The first three are saved routing results from 18 October 2026. Requests for Dalanguiring, Gueteb, Pasibi West and Real did not return usable results, so their travel times use this explicit fallback model:

Modeled road distance = straight-line distance x 1.4
Travel minutes = modeled road distance / 30 km/h x 60

The origin is the saved sample station marker at 15.8222000, 120.3297000. A live database location lookup did not complete; the station position is not independently verified. Destinations use the saved barangay hall coordinates below.

Barangay proxy	Latitude	Longitude	Travel source
Poblacion	15.8230293	120.3280002	Geoapify estimate
Bayaoas	15.8329772	120.3536367	Geoapify estimate
Pasibi East	15.8573403	120.3797199	Geoapify estimate
Dalanguiring	15.8383857	120.3312886	Distance/speed model
Gueteb	15.8455888	120.3537922	Distance/speed model
Pasibi West	15.8511054	120.3677424	Distance/speed model
Real	15.8066858	120.3472745	Distance/speed model
Angatel	15.8117067	120.3413576	Geoapify estimate

A barangay hall is a location proxy, not a verified historical fire site. These coordinates do not demonstrate that the actual incident occurred within 300 metres. Descriptions naming sitios, a school or a farm have not been independently geolocated.

Arrival-to-fire-out scenario

Each record receives an integer duration from 10 to 30 minutes using fixed random seed 20261021. These are synthetic values authorized for the documentation scenario. Low severity and one responding team are user-supplied assumptions; neither determines a measured suppression duration. H8 is described in the source notes as a large storage fire, so a uniform low-severity interpretation is not established by the records.

Sources: saved historical database snapshot; user-provided incident extract and fire-out interpretation; SampleDefaultDataSeeder.php; UrbiztondoBarangayHallSeeder.php; saved Geoapify routing results; historical-incident-interval-estimates.json. Seeders were read only, never run.

Reconstructed timeline

The recorded time is treated as fire out according to your clarification. Arrival, dispatch and report timestamps below are reconstructed scenario values, not original dispatch logs.

Arrival = fire out - generated suppression duration
Dispatch = arrival - estimated travel duration
Report = dispatch - assumed 2 minutes

Dates remain as stored, including first-of-month placeholders. Times are shown without timezone conversion. Where fire-out time is missing, timestamps remain unavailable. Timestamps are displayed to whole seconds, as stored in the estimate export.

ID	Synthetic report	Synthetic dispatch	Synthetic arrival	Fire out*
H1	2023-01-01 17:08:24	2023-01-01 17:10:24	2023-01-01 17:11:00	2023-01-01 17:38:00

*Fire out uses the original incident date/time reinterpreted by the user. The database field itself was not renamed or changed. H6, H7 and H9 have no recorded time, so their timelines cannot be reconstructed. Their generated intervals still contribute to the scenario averages.

Recommended next reviews

1. Confirm the operational fire-station pin and the exact historical incident locations.
2. Replace generated intervals with verified dispatch, arrival and fire-out logs.
3. Review the low-severity assumption, particularly the H8 storage fire.

The original estimate JSON is embedded in this PDF as historical-incident-interval-estimates.json. A PDF reader with an Attachments panel can open it.
